

How does $SU(2)$ represent rotations?

Daniel Corper

July 2026

1 Introduction

Normally we consider n -dimensional rotations to be associated with $SO(n)$, but as we know, 2-dimensional rotations can also be characterised with unit length complex numbers. This implies the following isomorphism:

$$U(1) \cong SO(2) \quad (1)$$

Exponentiating the $\mathfrak{u}(1)$ basis vector i generates these rotations. The isomorphism to $\mathfrak{so}(2)$ yields a matrix representation of i , which can be exponentiated to produce a 2-dimensional rotation matrix.

2 Quaternions

The natural next step may be to ask whether an analogy can be drawn to quaternions.¹ Let us first probe how exactly we can use these to parametrise 3-dimensional rotations, consider first a quaternion $\mathbf{q}$ only of the coordinate $\mathbf{i}$, we will exponentiate this and use it to act on the $\mathbf{i}$ basis vector, logically, this should yield no change, after all, rotating an x -axis vector around the x -axis should change nothing.

$$\mathbf{q} = e^{\mathbf{i}\theta} = \cos \theta + \mathbf{i} \sin \theta \quad (2)$$

Applying the rotation yields:

$$\mathbf{q}\mathbf{i} = (\cos \theta + \mathbf{i} \sin \theta)\mathbf{i} = \mathbf{i} \cos \theta + \mathbf{i}^2 \sin \theta = \mathbf{i} \cos \theta - \sin \theta \quad (3)$$

Notice that we have run into a problem, there exists an extra dimension in this final expression, one that is not tied to $\mathbf{i}$. To amend this, we can instead apply a rotation of θ through two half-angle $\mathbf{q}$ rotations in the form:

$$\mathbf{i}' = (\mathbf{q}\mathbf{i})\mathbf{q}^{-1} \quad (4)$$

¹Quaternions are an example of hypercomplex numbers, an extension of complex numbers to higher dimensions.

Since $\mathbf{i}^{-1} = -\mathbf{i}$, we can find that:

$$(\mathbf{q}\mathbf{i})\mathbf{q}^{-1} = (\mathbf{i}\cos\theta/2 - \sin\theta/2)(\cos\theta/2 - \mathbf{i}\sin\theta/2) = \mathbf{i}(\cos^2\theta/2 + \sin^2\theta/2) = \mathbf{i} \quad (5)$$

This yields exactly what we want. By exponentiating any one of the $\mathbf{i}, \mathbf{j}, \mathbf{k}$ basis vectors of the quaternions, we can specify any 3-dimensional rotation.

3 The symplectic group $Sp(1)$

Just as unitary complex numbers live in $U(1)$, unitary complex numbers live in $Sp(1)$.² You may then expect the following isomorphism to hold:

$$Sp(1) \cong SO(3) \quad (7)$$

But in fact, this is not the case. We will see why a little bit later. For now though, we know that there is a valid isomorphism:

$$Sp(1) \cong SU(2) \quad (8)$$

Since $\mathbf{i}, \mathbf{j}, \mathbf{k}$ form a basis of the lie algebra $\mathfrak{sp}(1)$, we find that the basis vectors of $\mathfrak{su}(2)$ form a matrix representation of them. You may know already of these basis vectors, they are the Pauli matrices.

3.1 The 3-dimensional rotation group $SO(3)$

The structure of the Lie algebra $\mathfrak{so}(3)$ is found to be:

$$[J_i, J_j] = \varepsilon_{ijk} J_k \quad (9)$$

We find that the Lie algebra $\mathfrak{su}(2)$ is remarkably similar:

$$[\sigma_i, \sigma_j] = 2i\varepsilon_{ijk} \sigma_k \quad (10)$$

Therefore in scaling σ_i by $(2i)^{-1}$, we can obtain a representation of $SO(3)$ in terms of the Pauli matrices, and thus in terms of quaternions. We say the following isomorphism holds:

$$\mathfrak{so}(3) \cong \mathfrak{su}(2) \quad (11)$$

4 Rotations in $SU(2)$

We can now form an element of $SO(3)$ in terms of the scaled Pauli matrices, we can write this generally as:

$$R = \exp\left(\frac{\theta}{2i}\sigma \cdot \hat{n}\right) \quad (12)$$

² $Sp(1)$ is given as:

$$Sp(2n) = \{M_{2n \times 2n} : M^T J M = J\} \quad (6)$$

Where J is a skew symmetric bilinear form called the *symplectic* form.

Where $\sigma \cdot \hat{n}$ is given as:

$$\sigma \cdot \hat{n} = \sigma_x n_x + \sigma_y n_y + \sigma_z n_z \quad (13)$$

And $\hat{n}$ is the normal vector in the direction of the axis by which the rotation will proceed around. So we can already see here that rotations under the $SU(2)$ representation only individually give half of the power one may expect, this being a hint towards the unusual rotation properties of spinors.³ So, recalling the prior statement on how quaternion rotations must be performed (to preserve the structure of 3-dimensional space), provided a vector U , the full rotation under $SU(2)$ would be given as:

$$U \rightarrow U' = R^\dagger U R \quad (14)$$

5 Why $Sp(1) \not\cong SO(3)$?

Since we know that there exists an isomorphism between $Sp(1)$ and $SU(2)$, if there also existed one between $SU(2)$ and $SO(3)$ then our initial statement would hold. The reason that this is not the case lies in the unusual rotation property of quaternions, and thus the Pauli matrices. (Specified in section 2 and eqn 14.) Suppose an element $A \in SO(3)$ representing a unique rotation. It acts on an object V such that:

$$V \rightarrow V' = AV \quad (15)$$

That same rotation represented in $SU(2)$ uses the element $B \in SU(2)$ such that:

$$V \rightarrow V' = B^\dagger V B \quad (16)$$

But notice that $-B$ also gives the same rotation:

$$V \rightarrow V' = (-B^\dagger)V(-B) = B^\dagger V B \quad (17)$$

Therefore, there is not an isomorphism between $SU(2)$ and $SO(3)$ because the map is not 1-to-1. There are *two* valid elements of $SU(2)$ for any one in $SO(3)$. For this reason, we call $SU(2)$ the *double cover* of $SO(3)$.

³Recall that spinors represent spin-1/2 particles, and the Pauli matrices act as the spin operators for the spin-1/2 representation.
